November 15, 2005

Dear Colleague:

We are pleased to release the 2004 report, "STD Prevalence Monitoring and Expanded Chlamydia and Gonorrhea Screening in Los Angeles County Juvenile Hall Facilities." The Los Angeles County STD Program, in collaboration with the Los Angeles County Juvenile Court Health Services and the Los Angeles County Public Health Laboratory, has participated in the Centers for Disease Control and Prevention's Corrections STD Prevalence Monitoring Project since February 1997. This report summarizes the results of chlamydia and gonorrhea screening at Los Angeles County (LAC) juvenile halls from January 1, 2004 through December 31, 2004. The three detention facilities include Barry J. Nidorf, Central and Los Padrinos Juvenile Halls.

Rates of chlamydia and gonorrhea among detainees at LAC juvenile halls are among the highest of any group in the County. Incarcerated youth often have an earlier sexual debut, multiple sex partners, a history of sexual and physical abuse, have traded sex for drugs or money and engaged in other high-risk behaviors. These behaviors put them at significantly higher risk for STDs compared to non-incarcerated youth. In 2004, 1,458 (86% treated) cases of chlamydia, and 313 (81% treated) cases of gonorrhea were identified and treated at the three LAC juvenile detention facilities.

The STD Program has therefore made STD screening and treatment of these youth during their incarceration a top priority. Throughout 2004 universal screening for chlamydia and gonorrhea was routinely provided to all juvenile detainees upon admission to the facilities, and this project will continue in 2005. In addition, we will expand prevention efforts to reduce incidence of STDs and associated complications in this high-risk population.

Sincerely,

Peter R. Kerndt, MD, MPH

INTRODUCTION

DISEASE REPORTING

Sexually transmitted infections caused by *Chlamydia trachomatis* and *Neisseria gonorrhoeae* are overwhelmingly diseases of adolescents and young adults. In 2003, approximately 9,763 cases of chlamydia were reported among adolescents ages 15 to 19 in Los Angeles County, 84% of which occurred in females. Adolescent cases accounted for nearly 30% of all reported chlamydia cases, although persons in this age group represent only 8% of the population. Because of the asymptomatic nature of chlamydia and gonorrhea, most infections go undetected, allowing the chain of infectious transmission to continue. Left untreated in girls and young women, chlamydia infection develops into pelvic inflammatory disease in 20% to 40% of cases, frequently leading to chronic pelvic pain, infertility, and ectopic pregnancy, a leading cause of maternal death. Recent research also shows that individuals infected with sexually transmitted diseases (STDs) have a three- to five-fold increased risk of acquiring HIV if exposed. Among adolescents, detainees in the juvenile custody system are at very high risk for chlamydia and gonorrhea infection. Incarcerated adolescents are more likely to have experienced earlier sexual debut, have multiple sex partners, and have engaged in survival sex or prostitution than non-incarcerated adolescents.

STD PREVALENCE MONITORING

The Los Angeles County STD Program, in collaboration with LA County Juvenile Court Health Services and the LA County Public Health Laboratory, has participated in the Centers for Disease Control's (CDC) Jail STD Prevalence Monitoring Project since February 1997. Funding is provided by CDC through the Los Angeles County Infertility Prevention Project. Throughout this project, our main goals have been to increase the level of chlamydia and gonorrhea screening of persons entering juvenile custody facilities and to assess the prevalence of STDs among this population using a standardized epidemiologic approach.

Prior to the implementation of the intake STD urine screening project, only about 5% of males and 54% of females were tested for chlamydia and gonorrhea. So few were tested because half of all detainees were unable to make their scheduled physical exam since they had been released, transferred to another facility, or were in court. Furthermore, boys who did receive their scheduled physical exams were not routinely screened for chlamydia or gonorrhea. Currently, data are being collected on all girls and boys admitted to each of the three County juvenile halls: Los Padrinos (LPJH), Barry J. Nidorf (BNJH) and Central (CJH). Thus, chlamydia and gonorrhea screening are being provided at all three LAC juvenile hall facilities.

Los Angeles County has the largest juvenile detention system in the United States. Adolescents from every corner of Los Angeles County are admitted on an ongoing basis to one of the three juvenile halls. Upon admission, all detainees are taken directly to the hall's infirmary where they go through a standard, general medical intake, including routine screening for syphilis. HIV testing may be performed at the patient's request. Juvenile detainees are scheduled to receive a complete physical examination where additional STD testing may occur. Currently, the intake STD urine screening project also provides all female and male detainees with routine screening for chlamydia and gonorrhea upon admission to a juvenile hall. Routine chlamydia screening using a highly accurate amplification-based assay began on all girls and a sample of boys admitted to LPJH in February 1997. In June 1999, routine chlamydia screening at intake was initiated on all boys admitted to CJH. During April 2000, screening was expanded to include all boys admitted to LPJH, instead of boys admitted during a two-week interval each

month. Then in September 2002, all boys admitted to BNJH began to receive chlamydia screening as well. Since September 2002, the Public Health Laboratory has been using the GenProbe Aptima 2 DNA amplification assay to analyze all urine specimens for chlamydia and gonorrhea. The Aptima 2 produces results for both chlamydia and gonorrhea simultaneously. Therefore, all specimens submitted are analyzed for gonorrhea as well as chlamydia. Data collected from those submitting specimens include basic demographic information and self-reported STD symptoms. In addition, results of chlamydia and gonorrhea tests and syphilis serology are collected, as are results for HIV serology, when available.

Appendix A: Technical Notes

DATA COLLECTION

Upon medical intake at admission, juvenile hall nurses order chlamydia and gonorrhea tests by completing laboratory requisition forms to send with the specimens to Public Health Laboratory (PHL). All requisition forms and subsequent lab results are then entered into the MYSIS database by PHL clerical staff. Hard copies of the requisition slips are stored at the PHL and picked up by STD Program staff. The data from this requisition slip (minus the laboratory results) are entered into the STD Program Juvenile Hall database by data entry staff. In preparation for data analyses, the MYSIS and Juvenile Hall datasets are then cleaned and merged into a final dataset by STD Program Epidemiology staff. Quarterly cumulative data from this project are formatted according to CDC's Infertility Prevention Project (IPP) guidelines, and sent to the Region IX IPP data manager and to CDC's Juvenile Hall STD Prevalence Monitoring Project.

Statistical Analysis Software (SAS) 8.2 was used to analyze data for this report.

Appendix B: Clinical Description of Chlamydia and Gonorrhea

California State law (California Administrative Code, Title 17, Public Health, Section 2500, 1996) requires all health care providers to report selected communicable diseases to local health departments. Six of these diseases are reported directly to the County STD Program using the STD Confidential Morbidity Report (STD CMR, Rev. 11/03). These six include: chlamydia, gonorrhea, syphilis, non-gonococcal/non-chlamydial urethritis (NGU), non-gonococcal/non-chlamydial pelvic inflammatory disease, and chancroid. The following case definitions should assist physicians and other health care providers in the reporting process. The clinical description for each disease is brief; a more thorough discussion can be found in **Sexually Transmitted Diseases** (2nd Edition, 1990) by Holmes, et al. STD Program staff is available to answer any questions you may have concerning STD case definitions and STD reporting requirements. Two of the six most frequently reported STDs are diagnosed as follows:

CHLAMYDIA

1. Clinical description

Presence of mucopurulent cervical, urethral, or rectal discharge; epididymitis, salpingitis, or PID in adults; conjunctivitis or pneumonia in infants born to mothers with untreated infection. Asymptomatic infections are common.

2. Criteria for diagnosis

Laboratory identification of *Chlamydia trachomatis* infection by culture, antigen detection, or nucleic acid detection (amplified or non-amplified) methods.

GONORRHEA

1. Clinical description

Presence of purulent cervical, urethral, or rectal discharge; epididymitis, pharyngitis, salpingitis, or PID in adults; conjunctivitis in neonates born to mothers with untreated infection. Asymptomatic infections are common.

2. Criteria for diagnosis

Compatible clinical picture and sexual exposure to a person infected with *N. gonorrhoeae*, OR a, b, or c.

- a. Observation of Gram negative intracellular diplococci in urethral specimen from a male,
- b. Isolation of typical gram-negative, oxidase positive diplococci from a clinical specimen,
- c. Laboratory identification of *N. gonorrhoeae* infection by culture, antigen detection, or nucleic acid detection (amplified or non-amplified) methods.

Appendix C: Laboratory Tests for Chlamydia and Gonorrhea

The Los Angeles County (DHS) Public Health Laboratory detects *Chlamydia trachomatis* and *Neisseria gonorrhoeae* in urine using nucleic acid amplification tests (NAATs). Such tests can detect and exponentially amplify as few as one copy of DNA or RNA in a clinical specimen. During the reporting period, the Public Health Laboratory used the Aptima Combo 2 Assay (Gen-Probe, Inc., San Diego, CA). A brief explanation of the assay follows.

The Aptima Combo 2 targets rRNA. This newer assay simultaneously tests for chlamydia and gonorrhea in the same specimen. It uses three technologies: target capture, transcription-mediated amplification (TMA), and dual kinetic assay (DKA). Target capture is used to separate the target sequence from other substances. Amplification is accomplished by TMA. Hybridization Protection Assay is used to label the amplified product with a molecule that emits a chemiluminescent signal. The light that is produced is detected using DKA. Signals for chlamydia and gonorrhea are simultaneously detected. Urine specimens must be added to the Gen-Probe transport tube, which contains a preservative. Specimens may be held at room temperature up to 30 days before testing. Frozen specimens may be held up to 90 days after collection. The Public Health Laboratory processes specimens within three days after the specimen arrives in the laboratory.
